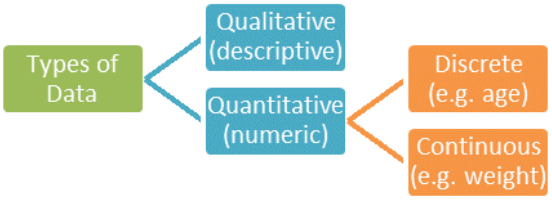
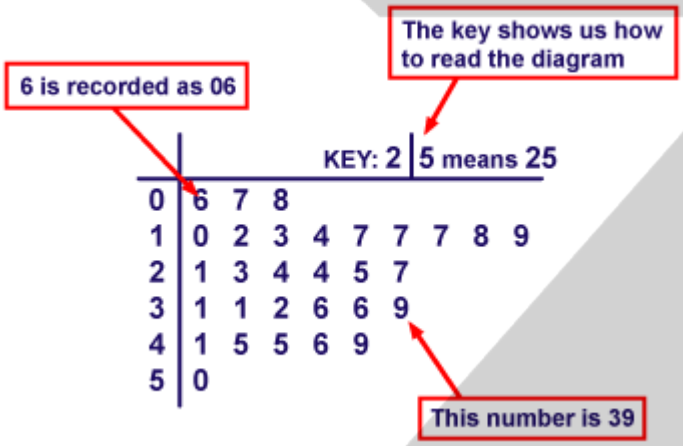
1. Representation of Data

1.1. Types of Data



1.2. Stem-and-Leaf Diagrams

- Used to represent data in its original form
- Each piece of data split into 2 parts; stem & leaf
- Leaf can only by 1 digit and should be written in ascending order
- Always include a key on your diagram



- **Advantage:** contains accuracy of original data

Back-to-back stem-and-leaf diagrams

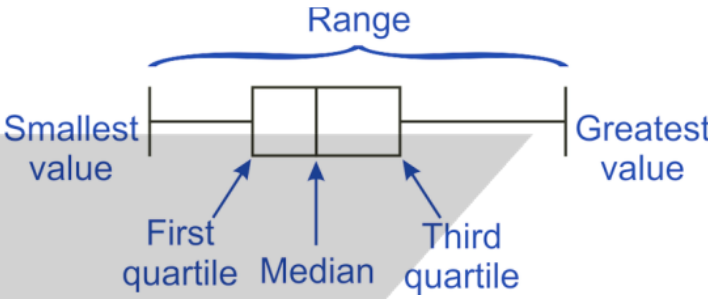
- Note the order of the left side

Female		Male
7 6	0	1 4 5
9 8 8 4 2	1	0 2 3 4 4 8
6 6 5 5 5 4	2	2 7 7 9
5 3 3 3 2 1 0	3	0 0 0 3 6 8
	4	0

Key : 3 | 1 | 4 represents
13 Female
14 Male

1.3. Box-and-Whisker Plots

- Five figure summary:
  - Lowest and highest values
  - Lower and upper quartiles
  - Median
- Mean & standard deviation most useful when data roughly symmetrical & contains no outliers
- Median and interquartile range typically used if data skewed or if there are outliers.



- **Advantage:** easily interpreted and comparisons can easily be made.

1.4. Histograms

- A bar chart which represents continuous data
- Bars have no space between them
- Area of each bar is proportional to frequency

$$Frequency = Frequency\ Density \times Class\ Width$$

- For open ended class width, double the size of previous class width and use this
- If range '$0-9$' then class width is '$-0.5 \le x \le 9.5$'

1.5. Cumulative Frequency Graphs

- Upper quartile $= 75$ th percentile value
- Lower quartile $= 25$ th percentile value
- Median $= 50$ th percentile value

$$Interquartile\ Range = Upper\ Quartile - Lower\ Quartile$$

- When finding the median and quartiles, draw in vertical and horizontal dashed lines on the graph, and find the corresponding x-axis value(s)
- Points are plotted at upper class boundaries
- Join points together with straight lines unless asked to draw a cumulative frequency curve

Key Points:

1. Add up preceding frequencies in the table to get the cumulative frequency
2. Plot points at the upper limit of the class interval

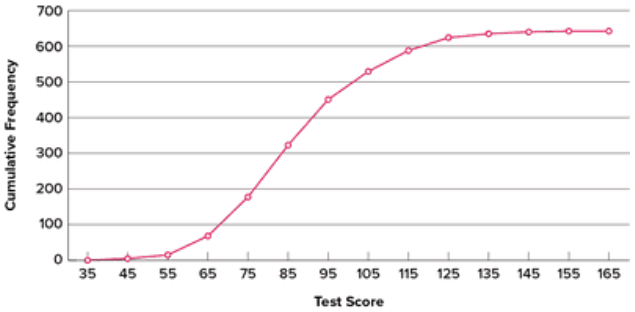
3. Ensure the curve through the points is smooth



1.6. Skewness

- **Symmetrical:** Median line lies in the middle of the box (i.e. UQ – median = median – LQ)
- **Positively skewed:** Median line lies closer to LQ than UQ (i.e. UQ – median > median – LQ)
- **Negatively skewed:** Median line lies closer to UQ than LQ (i.e. UQ – median < median – LQ)
